Introduction

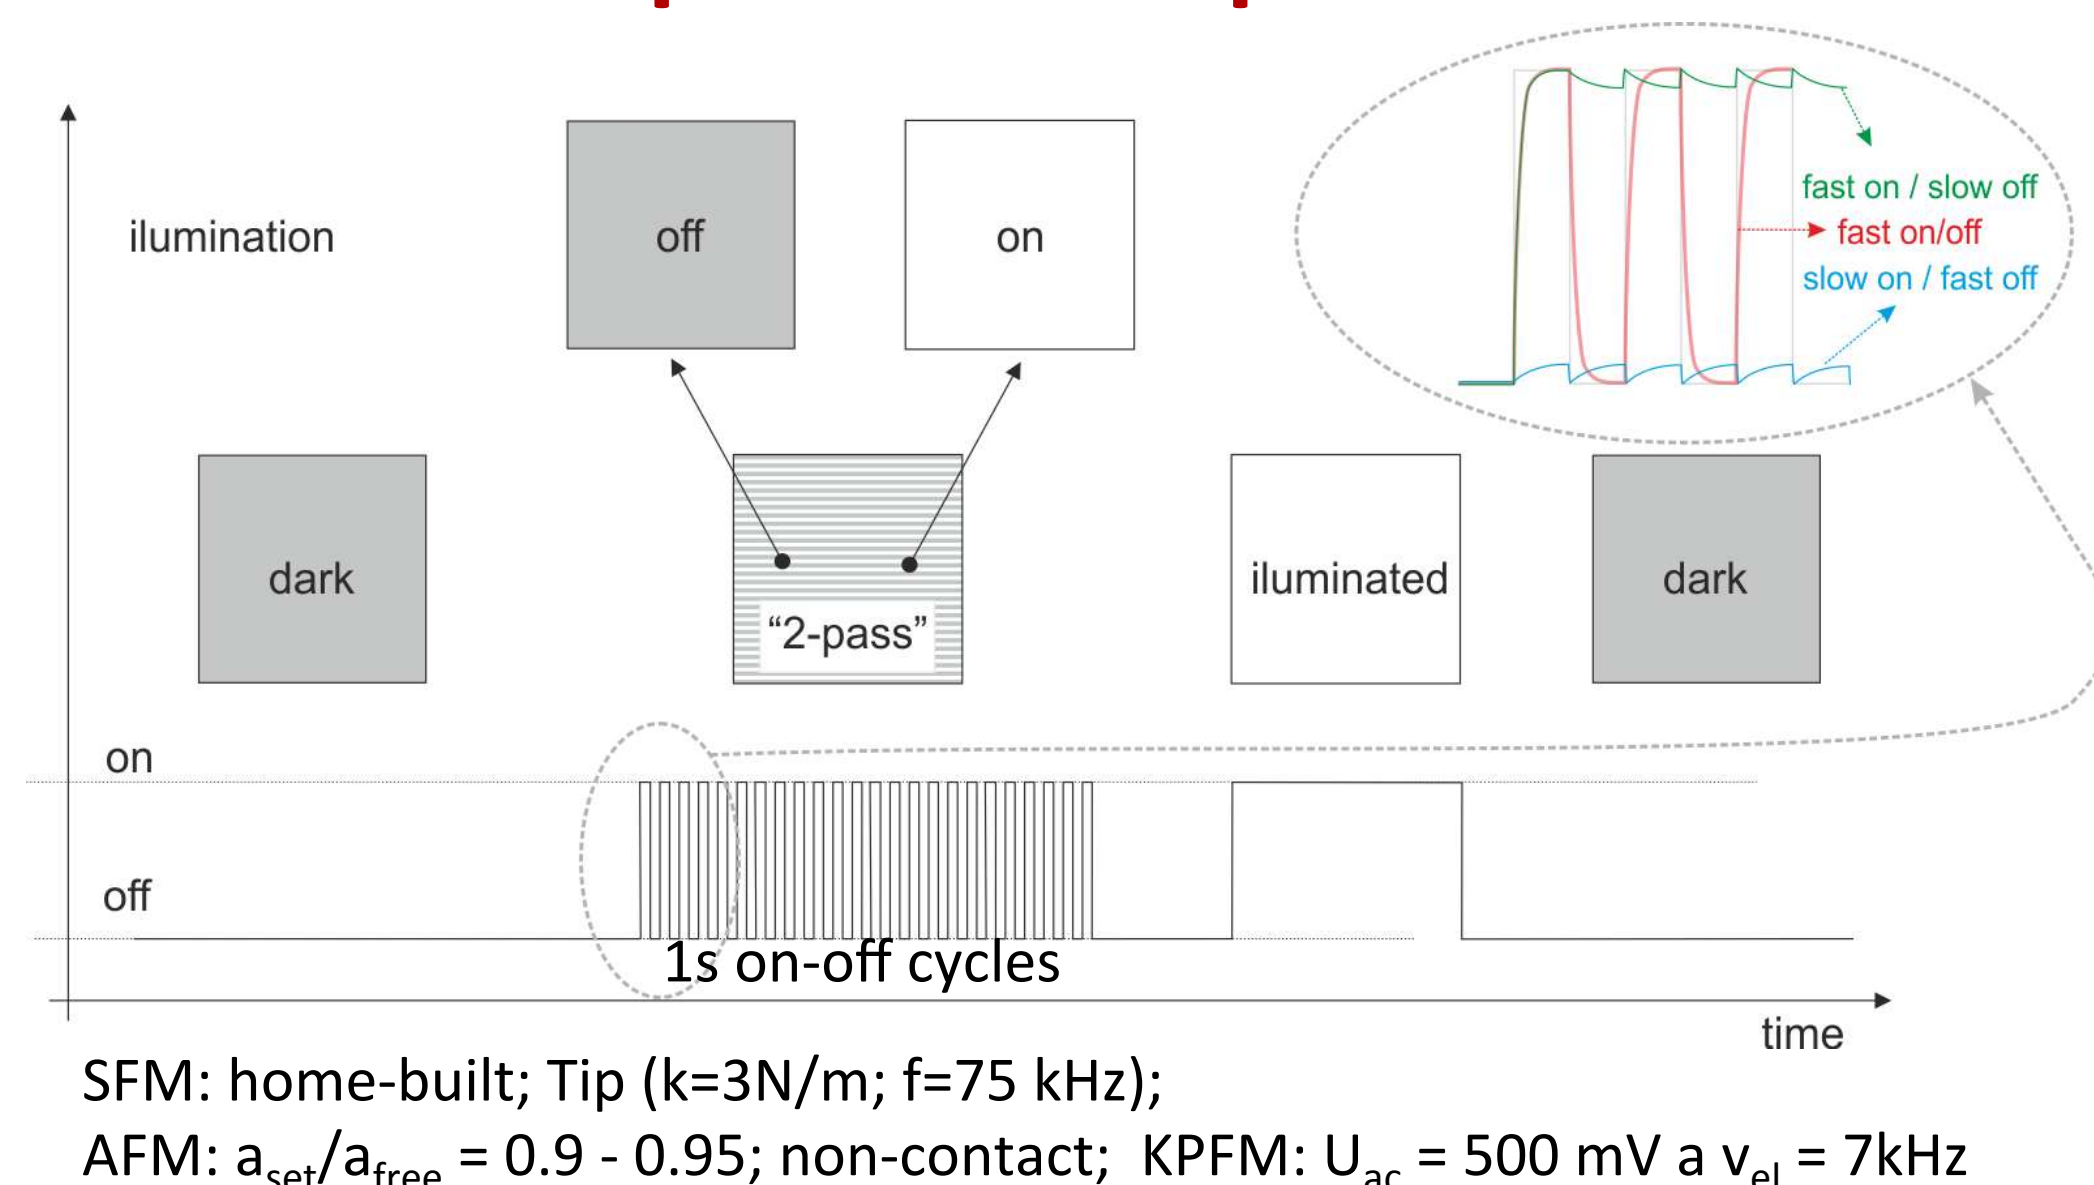

Graphene oxide (GO) is a chemically modified form of graphene containing many different types of oxygen functional groups on its basal plane and edges. Their presence imparts hydrophilicity and allows for ease of processing from water dispersions. We recently have shown that sheets of graphene oxide critically affect the aggregate structure of water dispersible nanoparticles P3HT_{NPs} and thus the performance of optoelectronic thin film devices.¹ In this work we elucidate the photogenerated charge transfer dynamics of (P3HT_{NPs}-GO) ensembles with defined aggregate structure across their interface by Kelvin Probe Force microscopy (KPFM).^{2,3}

Preparation of P3HT_{NPs}-GO ensembles

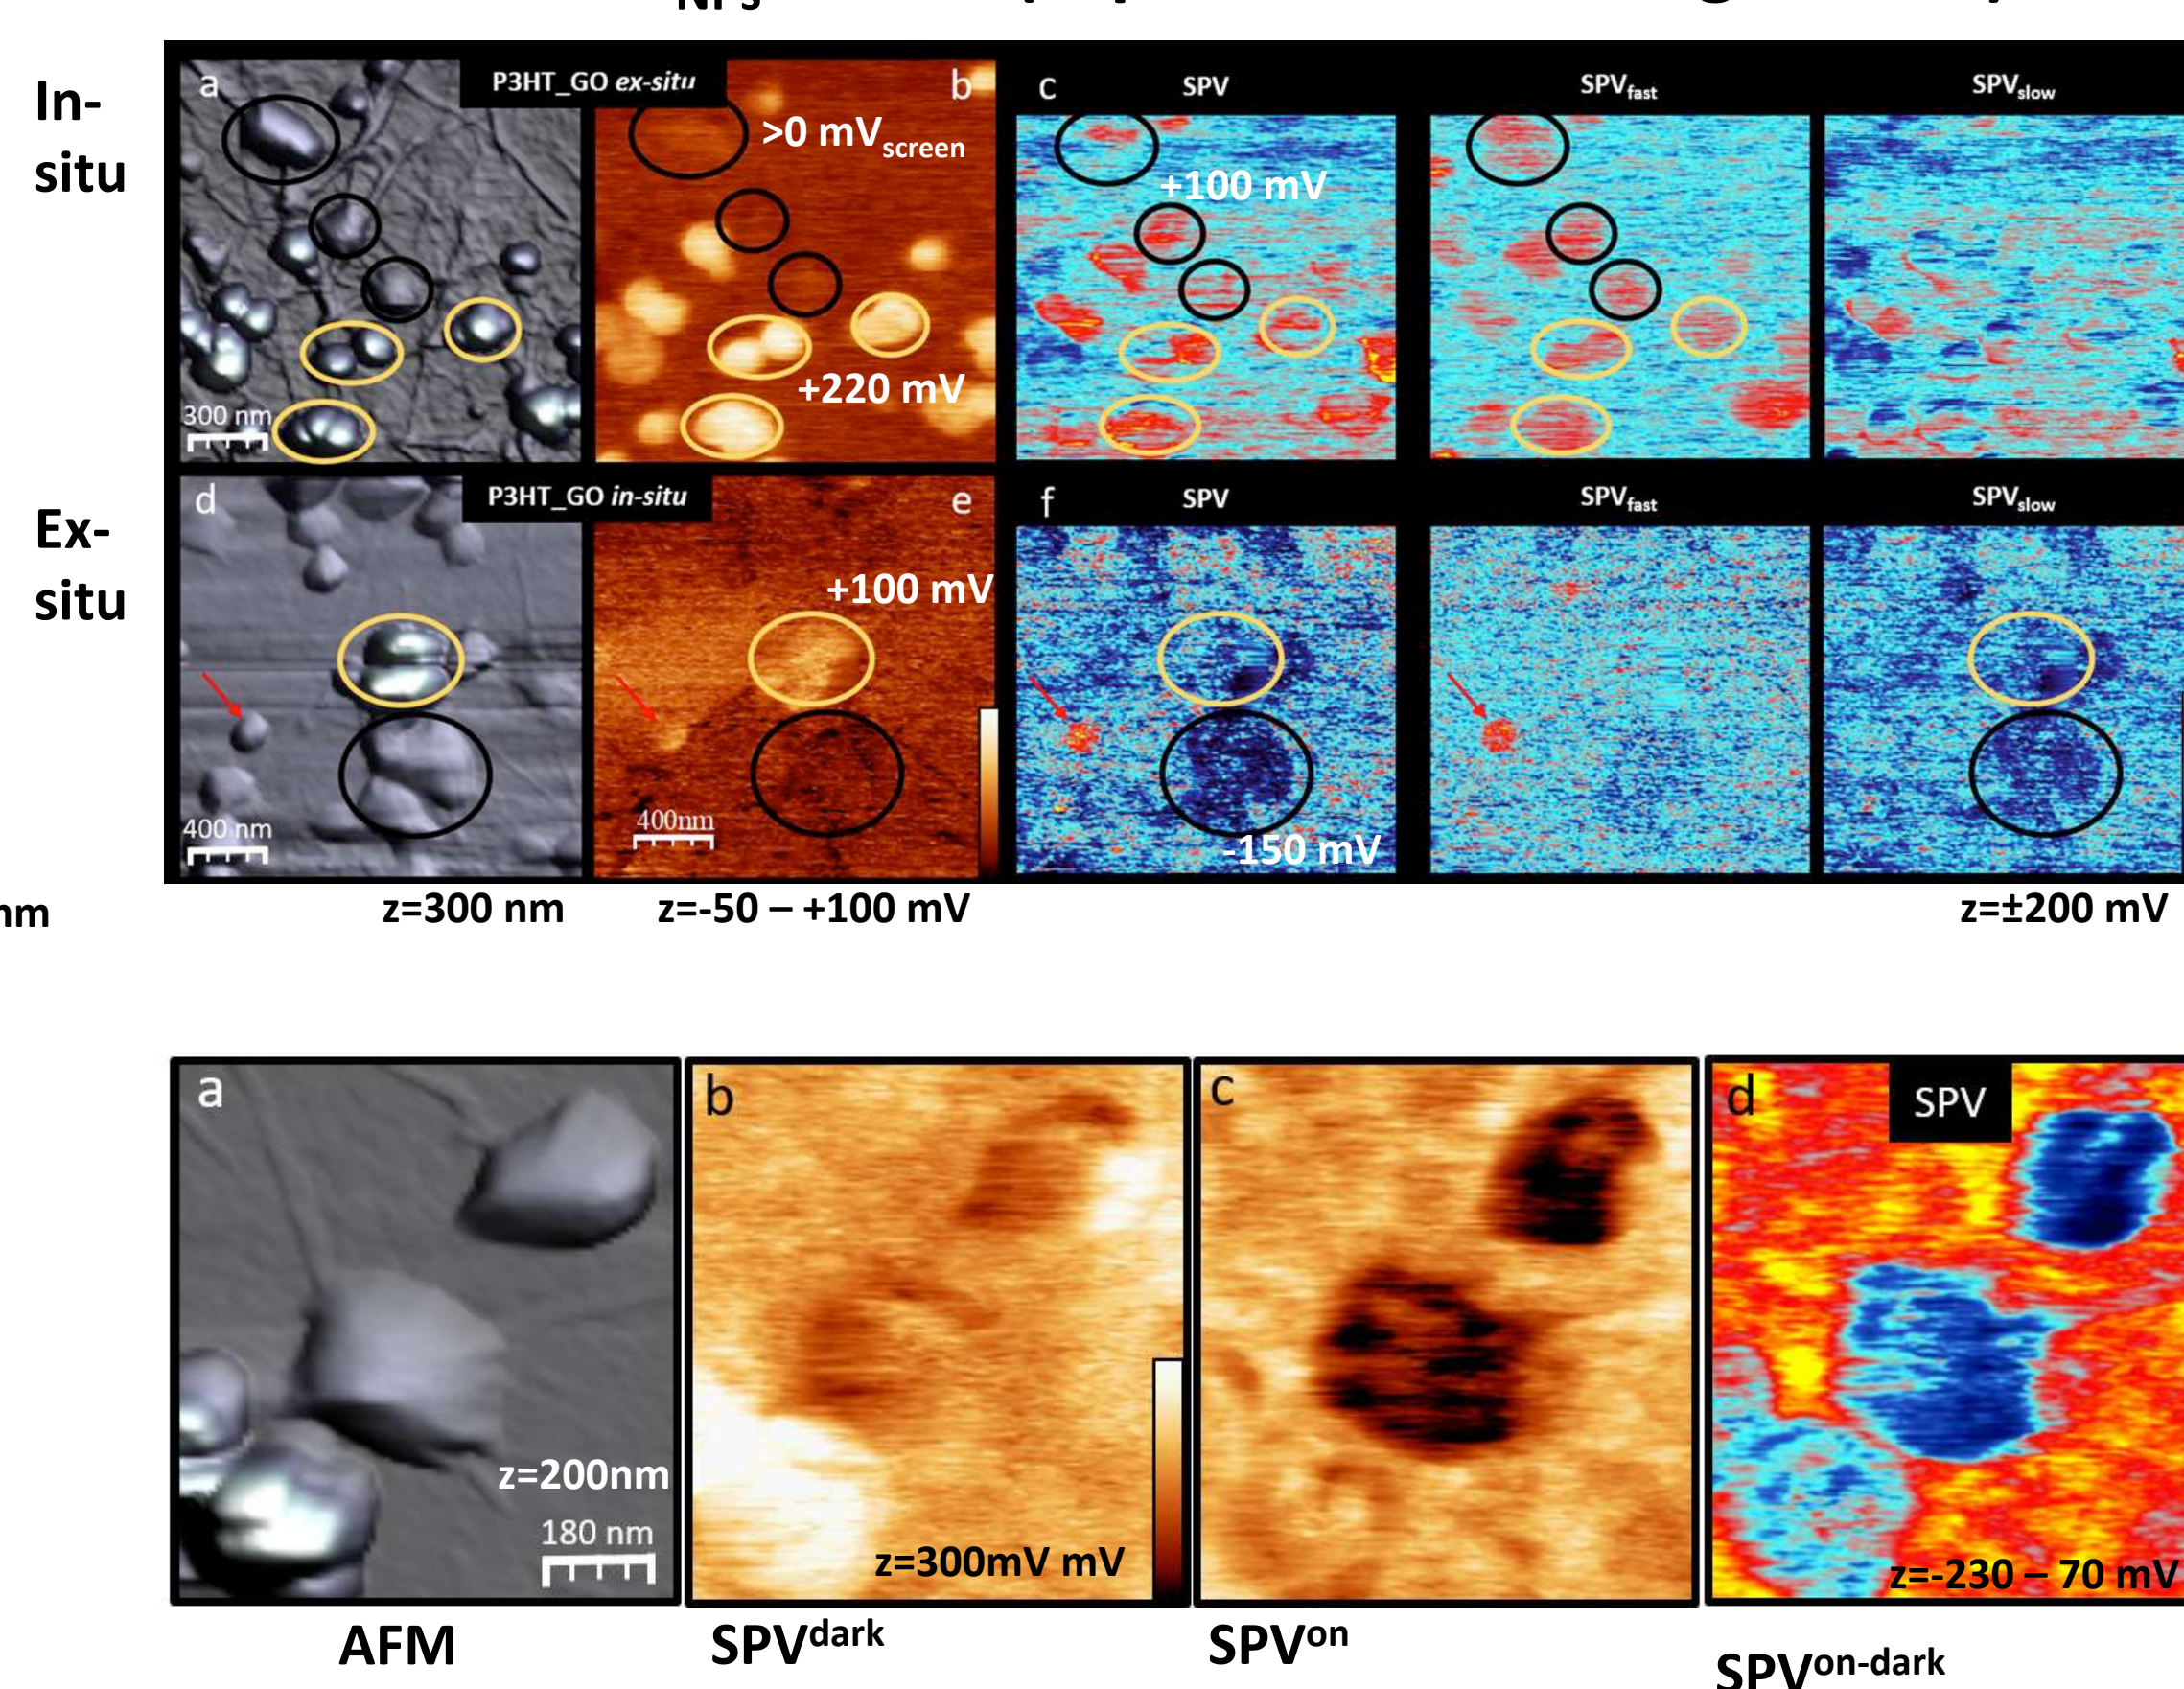

KPFM: Two-pass technique

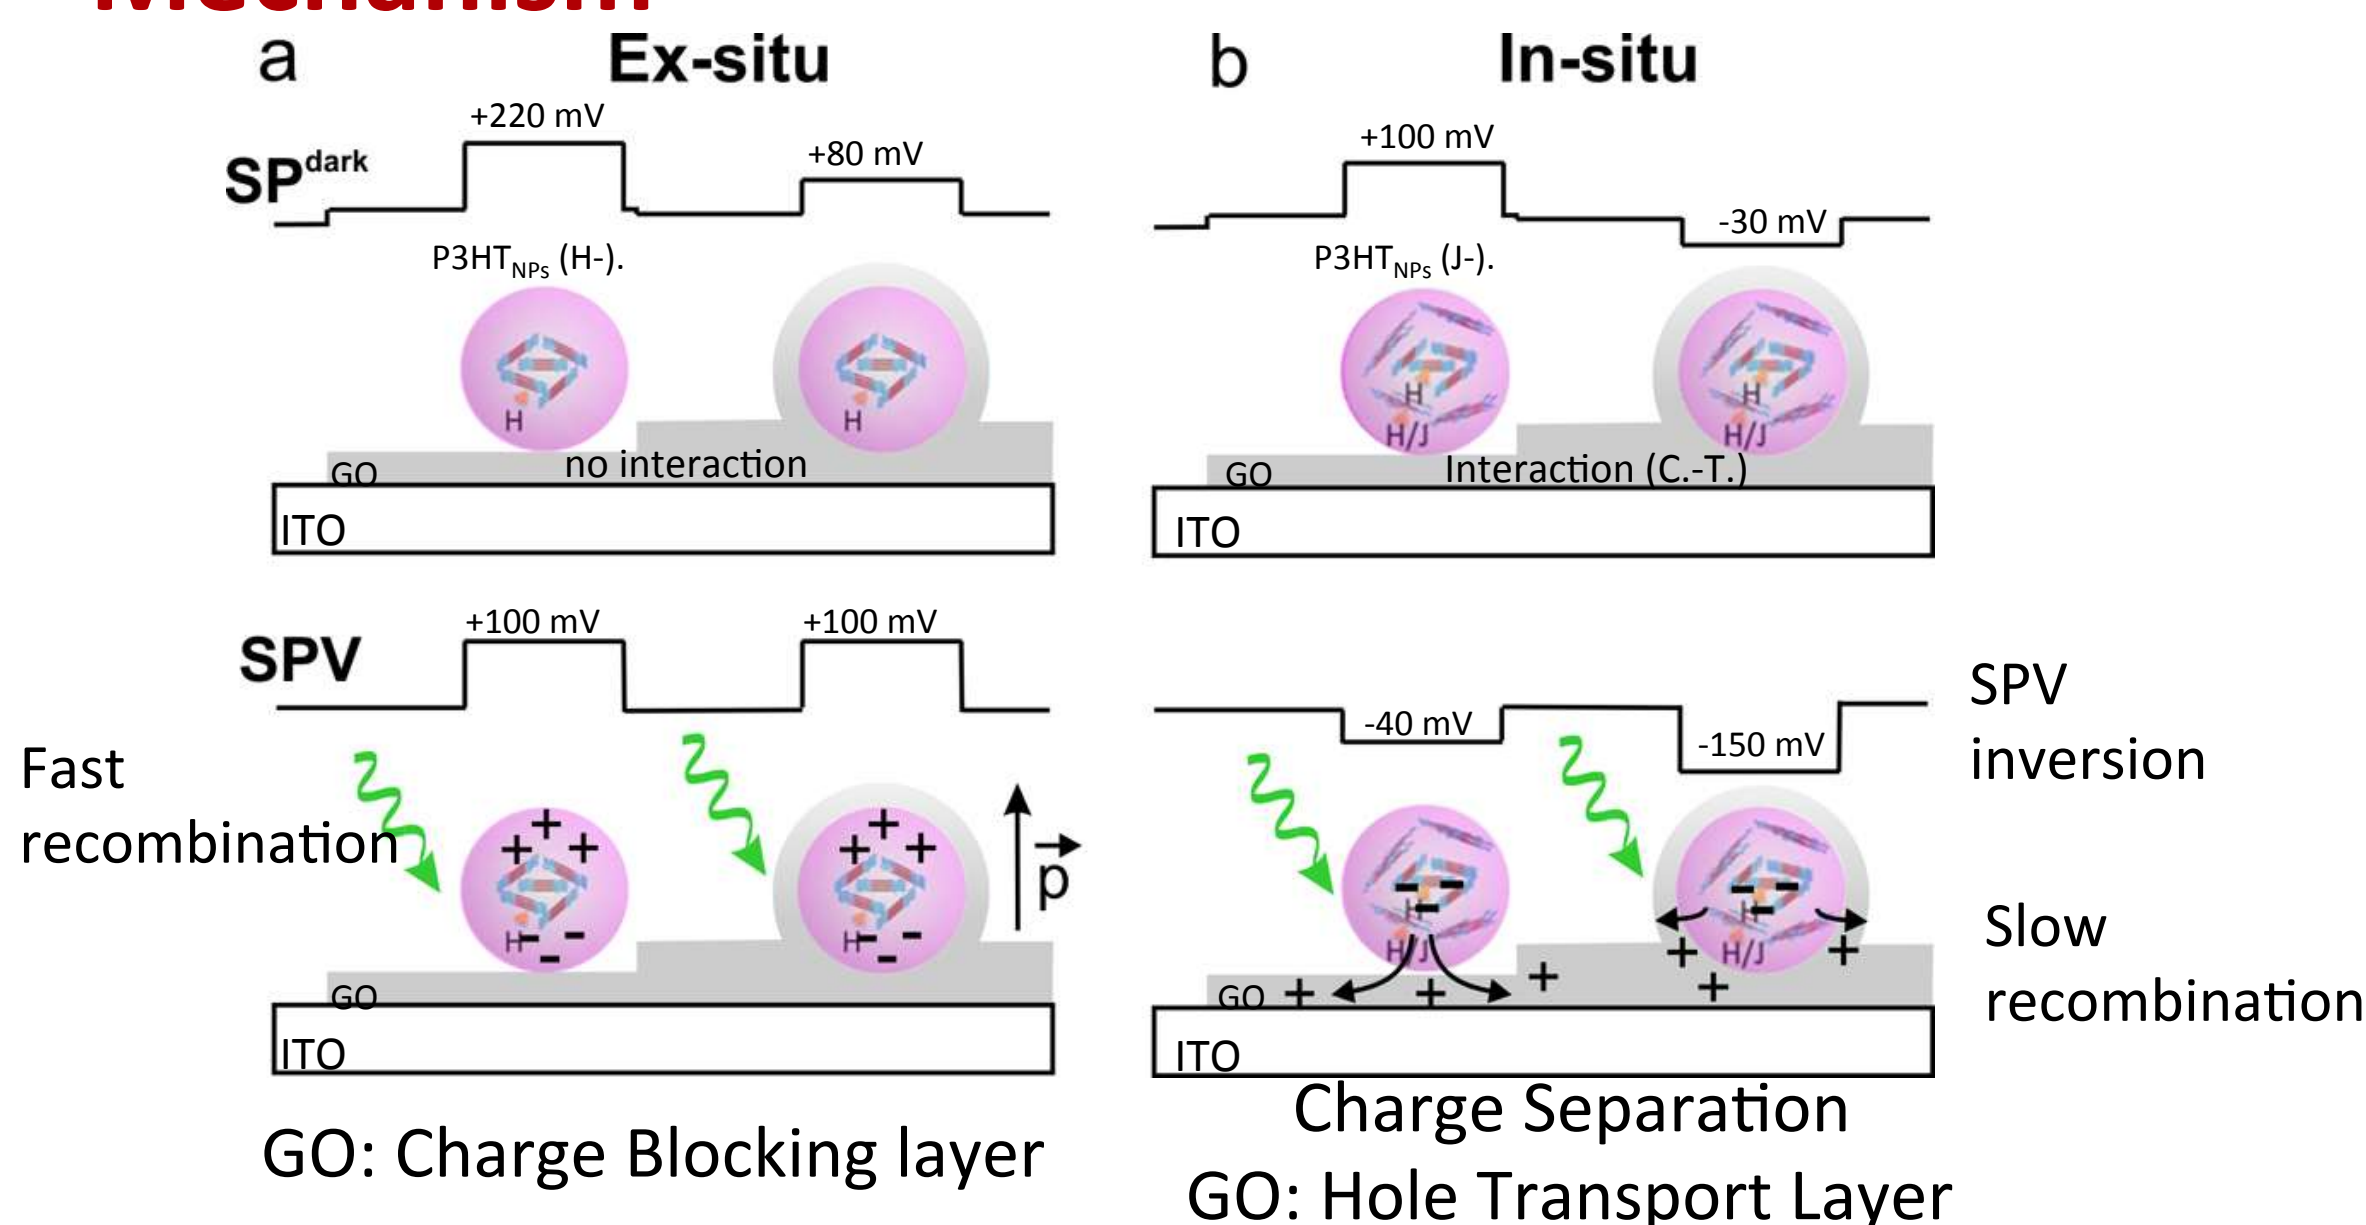

KPFM STUDIES: Surface potential (SP) and Surface photovoltage (SPV)

P3HT_{NPs} on GO (top and down configuration)

Mechanism

Conclusions

- GO acts as HTL
- P3HT_{NPs}-GO (in-situ): Photoactive layered system
- GO acts as CBL
- P3HT_{NPs} - GO (exsitu) non-interacting system
